

# Environmental Monitoring using IoT Devices

+

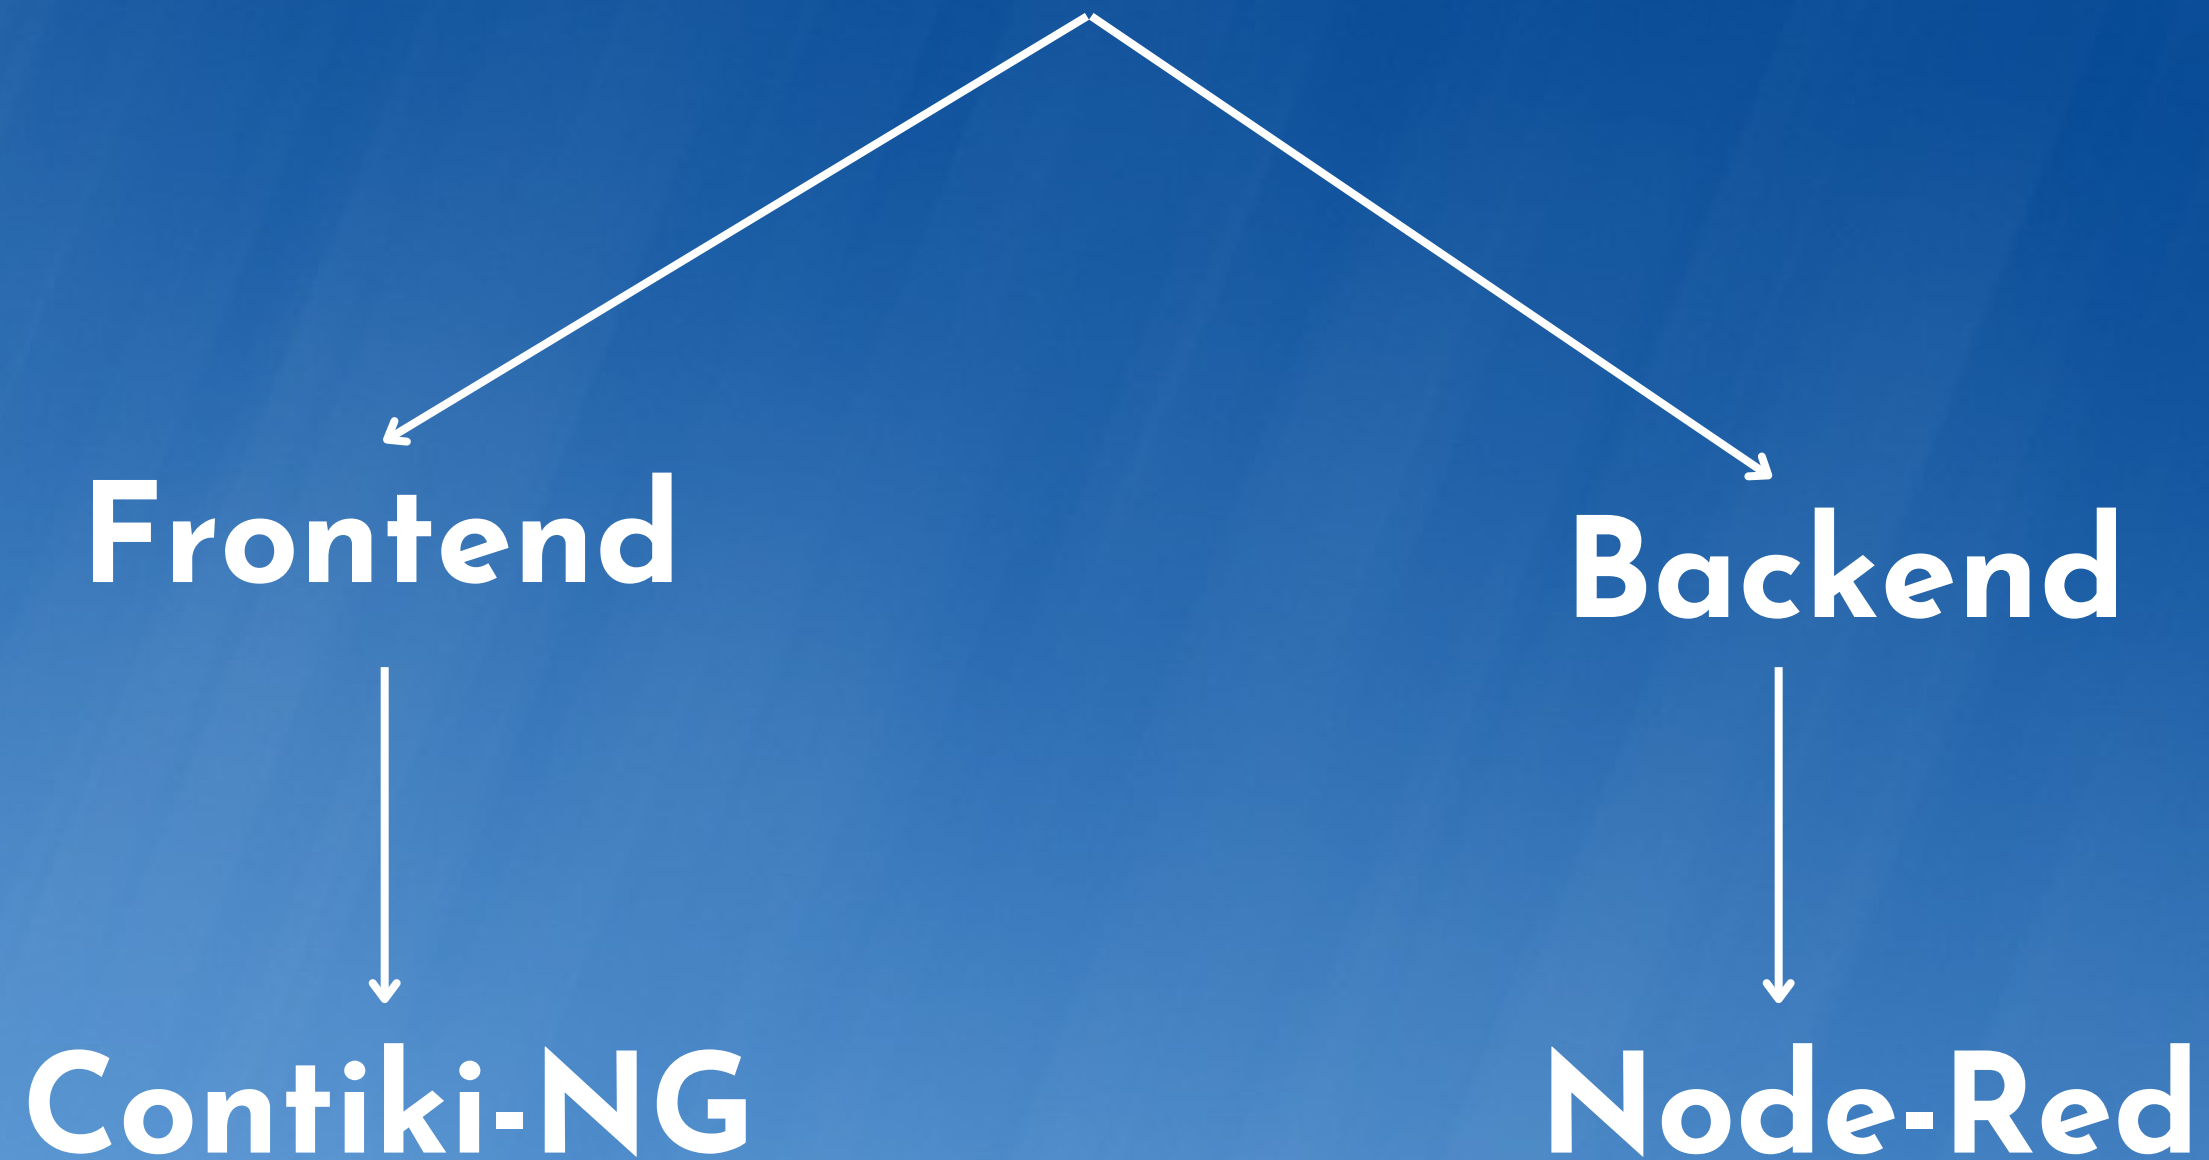

# Goals

- Network of IOT devices running Contiki-NG
- Readings of Temperature and humidity are reported to backend
- Backend logs maximum and minimum daily temperature and humidity for each month
- Persistent data

# Technologies

「Frontend」

# Assumptions

- Devices are constantly reachable from the border router either through one or multiple steps
- Simulation uses a *constant loss unit-disk graph model (CL-UDGM)* with interference range set to 0

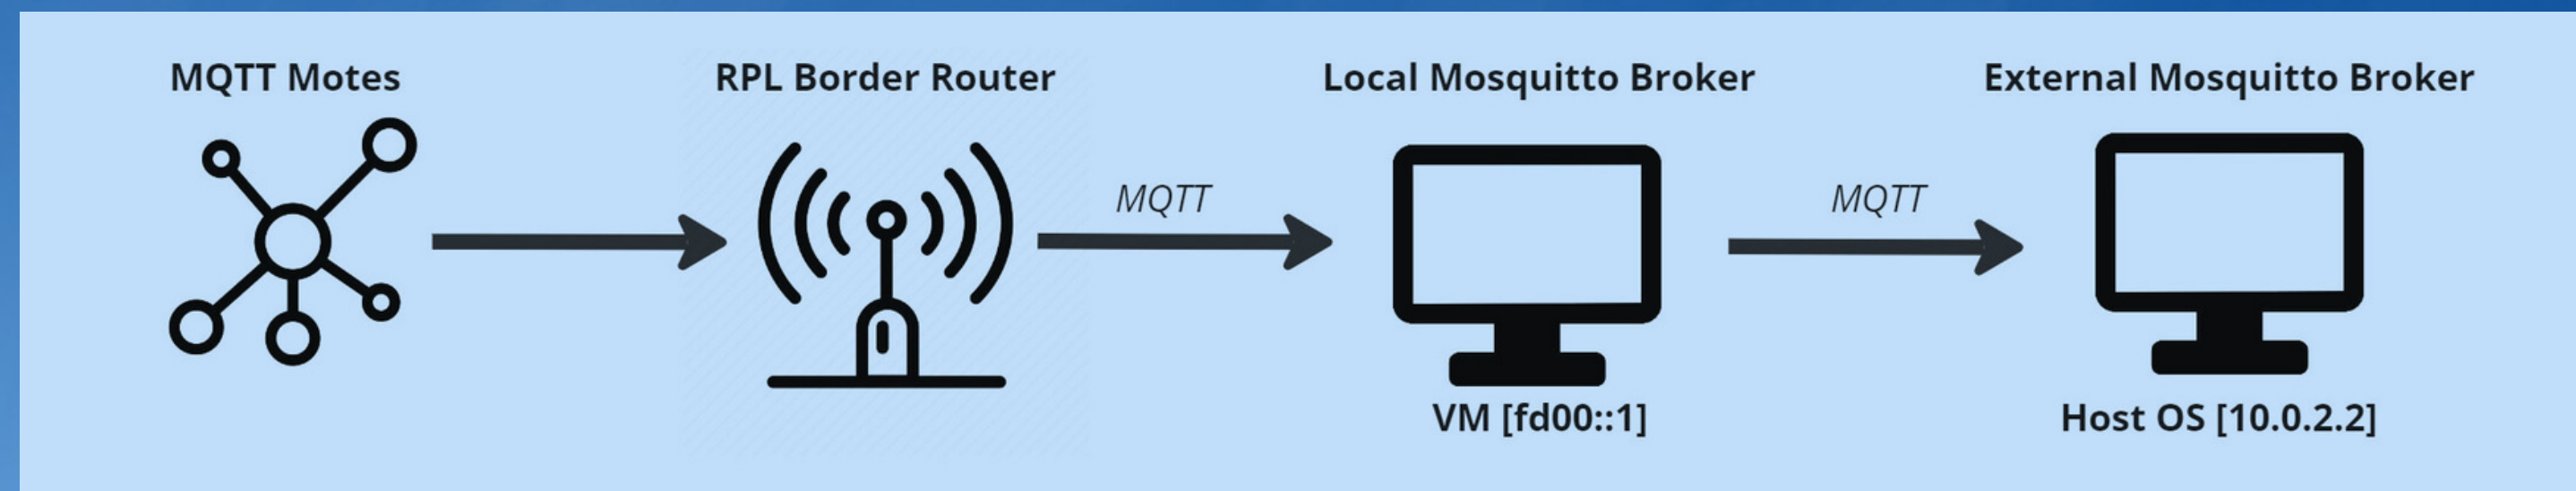

# Design

- Messages sent using MQTT with QoS set to zero
- Motes communicates using RPL tree protocol
- Two types of motes:
  - MQTT motes compute and send humidity and temperature readings
  - Root of the RPL tree
- MQTT motes saves in a buffer last six readings:
  - If last reading value is greater than a threshold it is sent
  - Else the average of the last six reading is sent

# Deployment

# Simulation

debug - Cooja: The Contiki Network Simulator

「Backend」

# Assumptions

- Single messages contain both temperature and humidity values
- Few readings can be lost without affecting overall result
- Arrival rate is low enough for updating a file every time a message arrives
- Messages arrive only with an equal of newer day

# Design

# Deployment

- When launching the backend the prestart flow should be launched
- The path of the file nodes should be changed using the desired path of the user
- Upon crashes nothing should be done, everything is automatically handled
